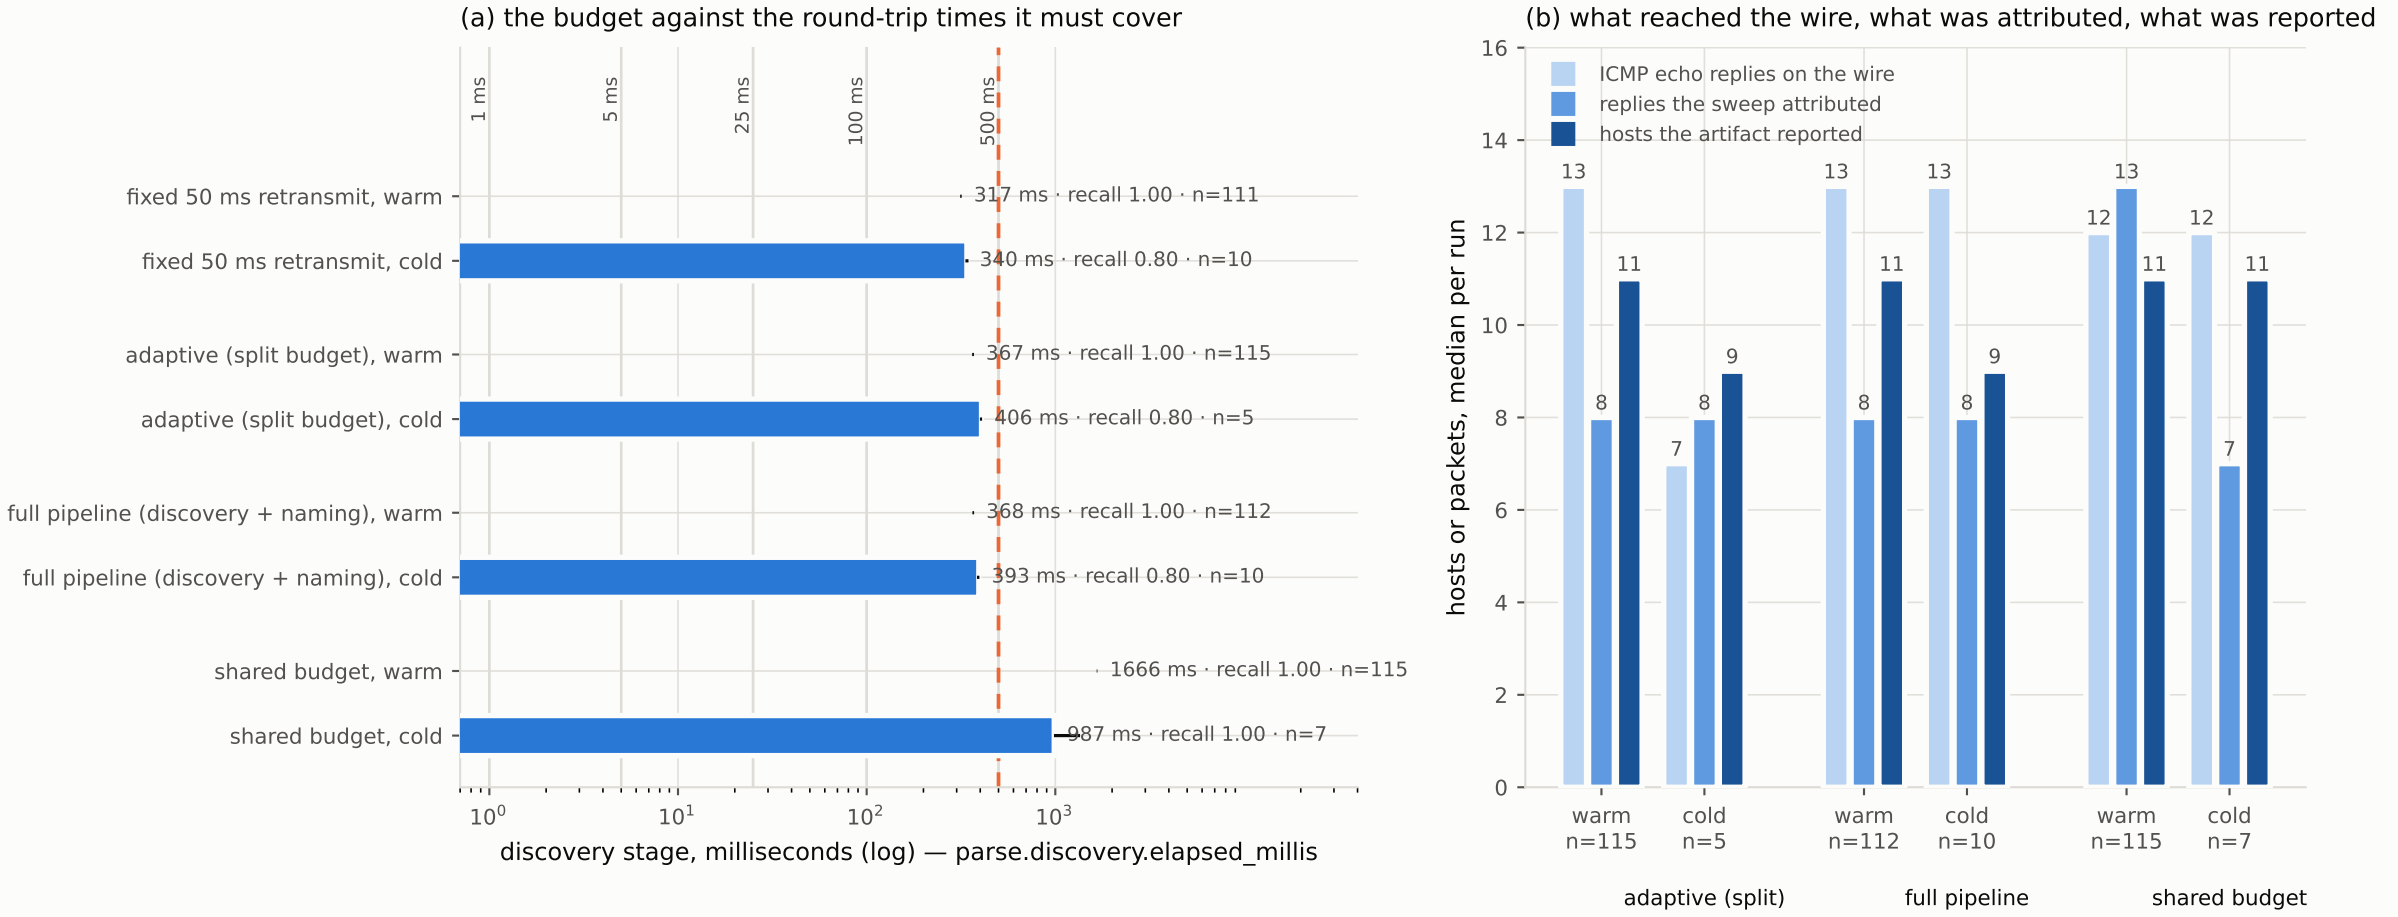
Figure 4 — the declaration budget is shorter than the slowest host



THEORY.md section 5 requires the declaration budget t to exceed the high quantile of the segment's round-trip times. The split budget declares at about 370 ms against a slowest responder at 500 ms. Cold, it reports 9 of 11 hosts. Warm, it reports 11 while attributing the same 8 replies — the two it did not hear come from the kernel neighbour table, which the block's flush empties. In ns.naming.full's 3.08 s cold runs the wire carries 13 echo replies and the artifact still reports 9: the late replies arrive inside the process and are not attributed. The shared budget declares at about 1 s and reports 11 in both arms.
