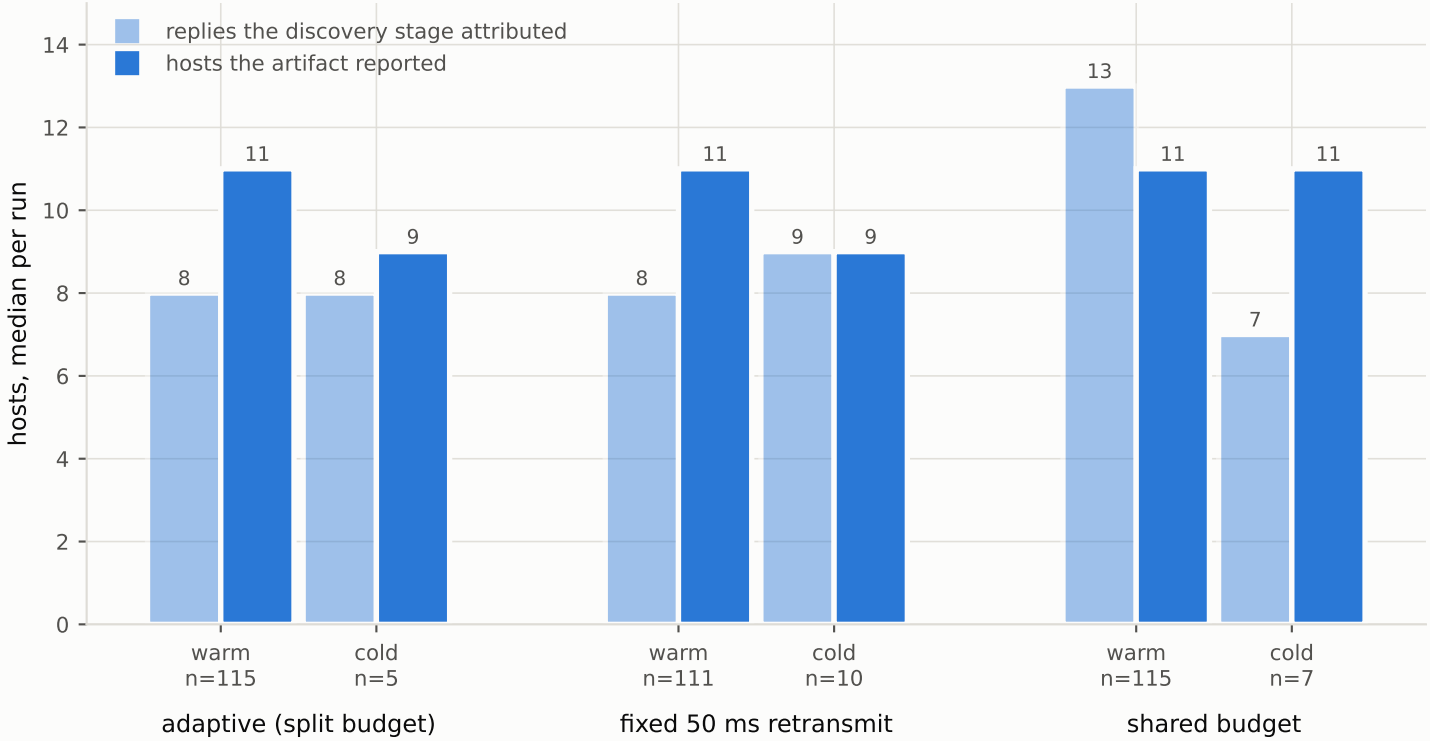
Figure 4 — the split budget reports hosts its sweep never heard


Both numbers are parse.discovery on every record. The split budget attributes the same 8 replies warm and cold — it never hears the two 500 ms responders in either arm — and reports 11 warm against 9 cold. The difference is the kernel neighbour table, which the previous run filled and the block's flush empties. The shared budget waits about a second, long enough for the 500 ms pair's ARP to land inside its own run.
